

St. Francis Institute of Technology, Mumbai-400 103
Department of Information Technology

A.Y. 2023-2024

Class: TE-ITA/B, Semester: V

Experiment – 7: To understand Terraform lifecycle, basic concepts / terminologies and install it on Windows/Linux machine.

Subject: **Advanced DevOps Lab**

1. **Aim:** To understand Terraform lifecycle, basic concepts/terminologies and install it on Windows /Linux machine.
2. **Objectives:** After study of this experiment, the student will be able to
 - Understand basic Terraform concepts
 - Perform installation of Terraform.
 - Write terraform scripts
3. **Outcomes:** After study of this experiment, the student will be able to
 - To be familiarized with infrastructure as code for provisioning, compliance, and management of any cloud infrastructure and d service.
4. **Prerequisite:** Fundamentals of cloud computing
5. **Requirements:** PC and Internet
6. **Pre-Experiment Exercise:**

Brief Theory:

Terraform

Terraform is an infrastructure as code (IaC) tool that allows you to build, change, and version infrastructure safely and efficiently. This includes low-level components such as compute instances, storage, and networking, as well as high-level components such as DNS entries, SaaS features, etc. Terraform can manage both existing service providers and custom in-house solutions.

Key Features

Infrastructure as Code:

You describe your infrastructure using Terraform's high-level configuration language in human- readable, declarative configuration files. This allows you to create a blueprint that you can version, share, and reuse.

Resource Graph

Terraform builds a resource graph and creates or modifies non-dependent resources in parallel. This allows Terraform to build resources as efficiently as possible and gives you greater insight into your infrastructure.

Change Automation

Terraform can apply complex change sets to your infrastructure with minimal human interaction. When you update configuration files, Terraform determines what changed and creates incremental execution plans that respect dependencies.

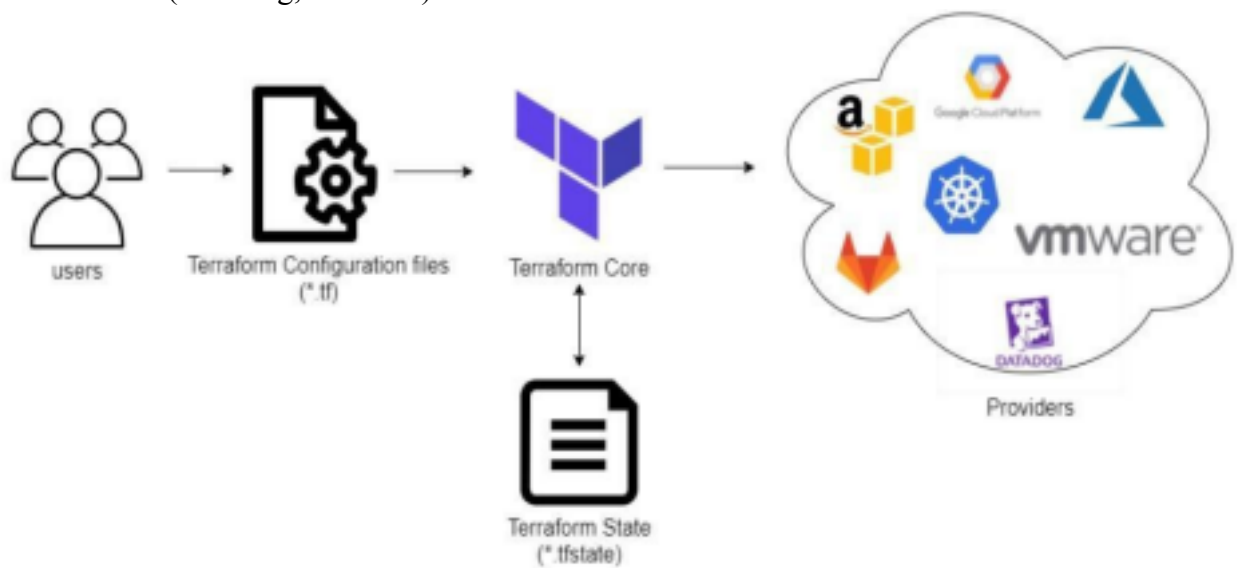

Terraform Life Cycle:

Terraform actually works, there's sort of two major components:

one is the **terraform core**: it takes the terraform configuration which is being provided by the user and then takes the terraform state which is managed by terraform itself. As such, this gets fed into the core that is responsible for figuring out what is that graph of our different resources for example how these different pieces relate to each other or what needs to be created/updated/destroyed, it does all the essential lifecycle management.

On the backside, terraform supports many different **providers**, such as: cloud providers (AWS,GCP,AZURE) and they also could be on-premise infrastructure (VMware, OpenStack.) But this support is not restricted or limited only to Infrastructure As A Service , terraform can

also manage higher level like Platform As A Service(Kubernetes, Lambdas..)or even Software As A Service (DataDog, GitHub..)

All of these are important pieces of the infrastructure, they are all part of the logical end-to-end delivery. Terraform has over a hundred providers for different technologies, and each provider gives terraform users access to their resources. It also gives you the

ability to create infrastructure at different levels.

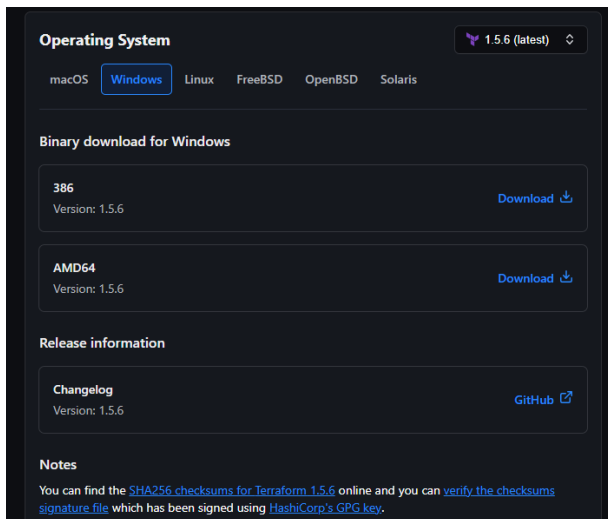

Terraform Core Concepts:

Below are the core concepts/terminologies used in Terraform:

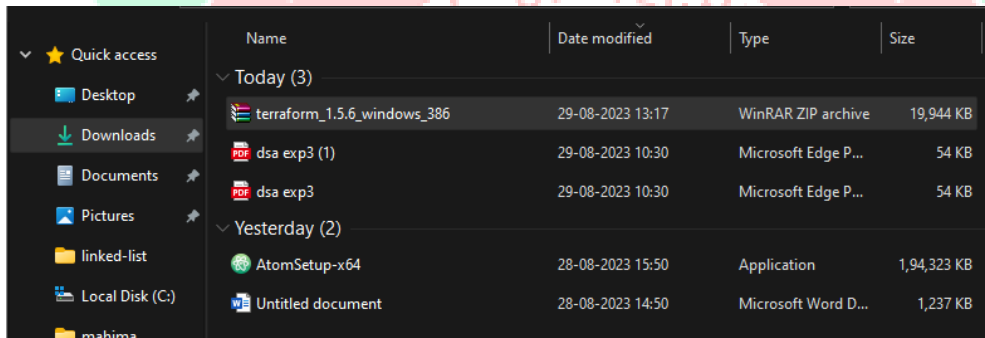

- **Variables:** Also used as input-variables, it is a key-value pair used by Terraform modules to allow customization.
- **Provider:** It is a plugin to interact with APIs of service and access its related resources.
- **Module:** It is a folder with Terraform templates where all the configurations are defined
- **State:** It consists of cached information about the infrastructure managed by Terraform and its related configurations.
- **Resources:** It refers to a block of one or more infrastructure objects (compute instances, virtual networks, etc.), which are used in configuring and managing the infrastructure.
- **Data Source:** It is implemented by providers to return information on external objects to terraform.
- **Output Values:** These are return values of a terraform module that can be used by other configurations.
- **Plan:** It is one of the stages where it determines what needs to be created, updated, or destroyed to move from the real/current state of the infrastructure to the desired state.
- **Apply:** It is one of the stages where it applies the changes in the real/current state of the infrastructure in order to move to the desired state.

7. Laboratory Exercise

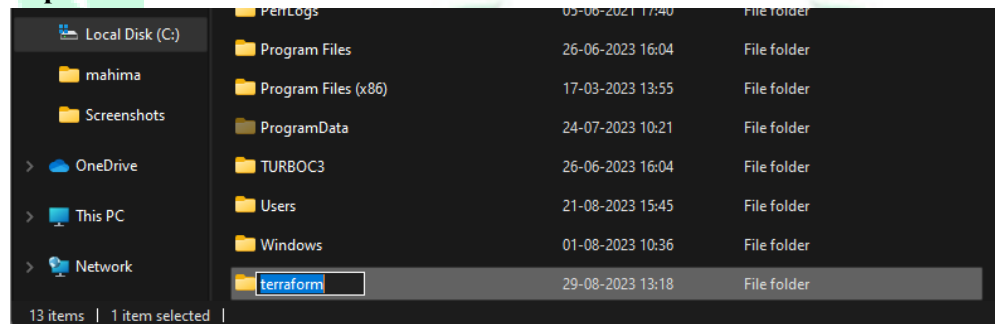

Step 1 : Download appropriate terraform package(.zip) from terraform.io/downloads.html for Windows

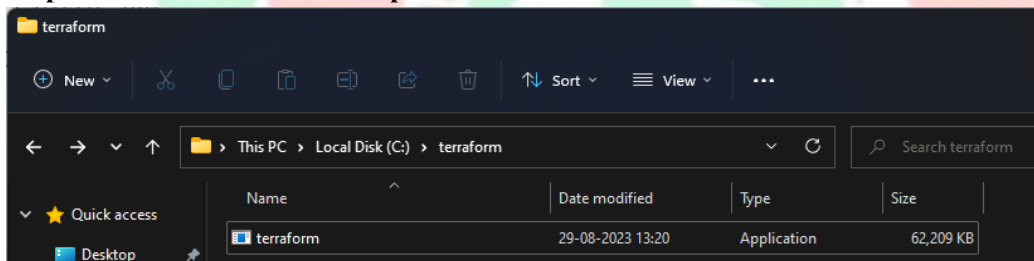

Step 2: Download Terraform for Windows 64-bit / (32-bit).

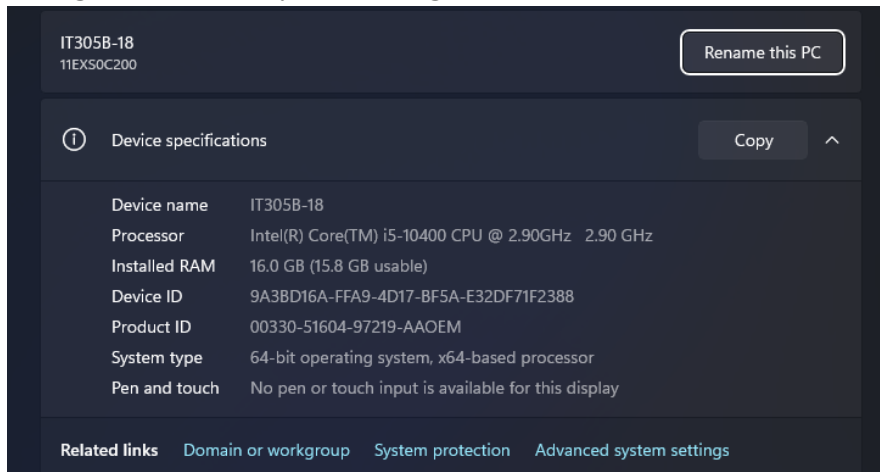

Step 3: Create a folder 'terraform' in drive C .

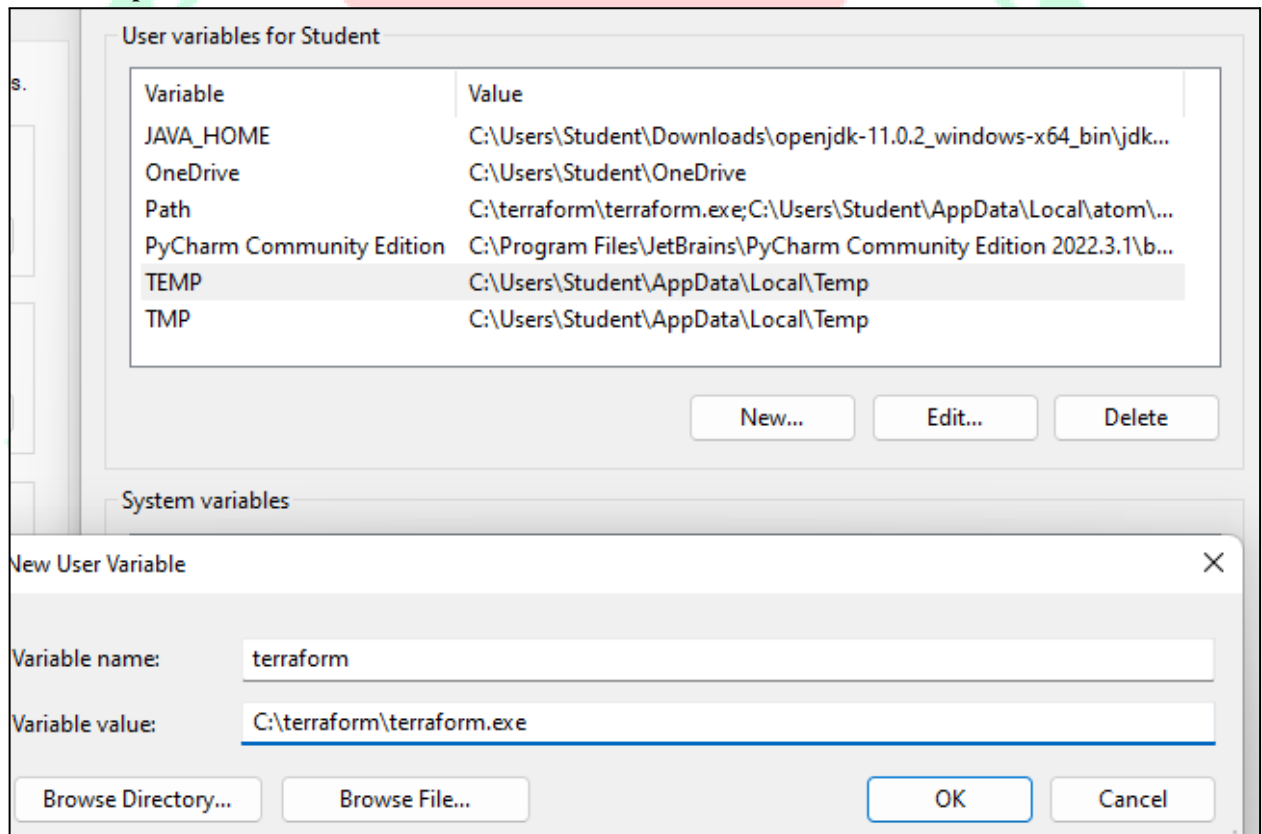

Step 4 : Extract downloaded zip in to this c:/terraform folder

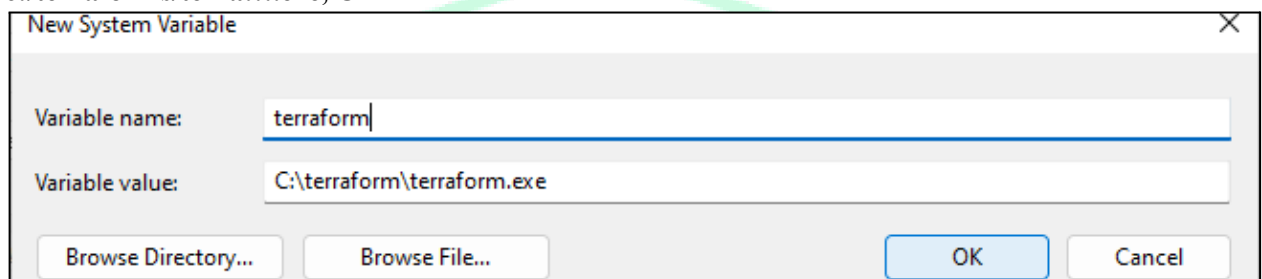

Step 5: Now we need to set path for terraform. Go to My computer/ This PC, right click, select properties, go to advanced system settings.

Step 6: click on environment variable

Step 7: click on New, give variable name = Path, click on browse directory, select c:/terraforms/terra....exe, OK

Step 8: Cross verify terraform installed properly or not . go to MS Powershell, run as a administrator

Step 9: Type terraform

```
Administrator: Windows PowerShell
Windows PowerShell
Copyright (C) Microsoft Corporation. All rights reserved.

Install the latest PowerShell for new features and improvements! https://aka.ms/PSWindows

PS C:\Windows\system32> terraform
```

Step 10: You will find init, validate, plan, apply and destroy options means you have installed terraform succesfully.

```
Administrator: Windows PowerShell
Windows PowerShell
Copyright (C) Microsoft Corporation. All rights reserved.

Install the latest PowerShell for new features and improvements! https://aka.ms/PSWindows

PS C:\Windows\system32> terraform
Usage: terraform [global options] <subcommand> [args]

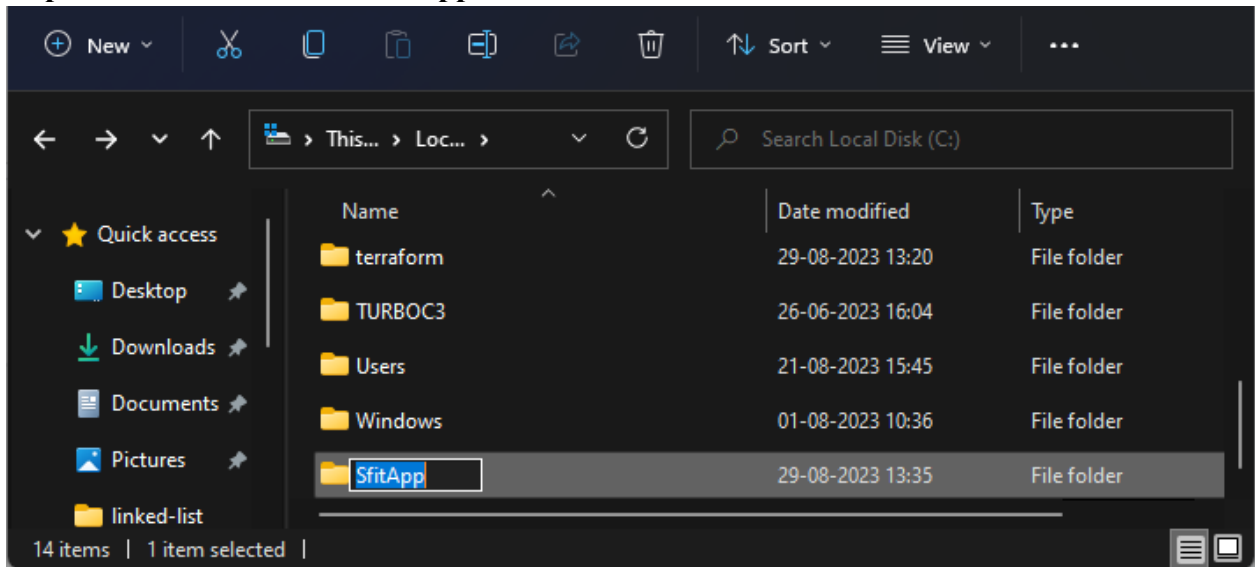

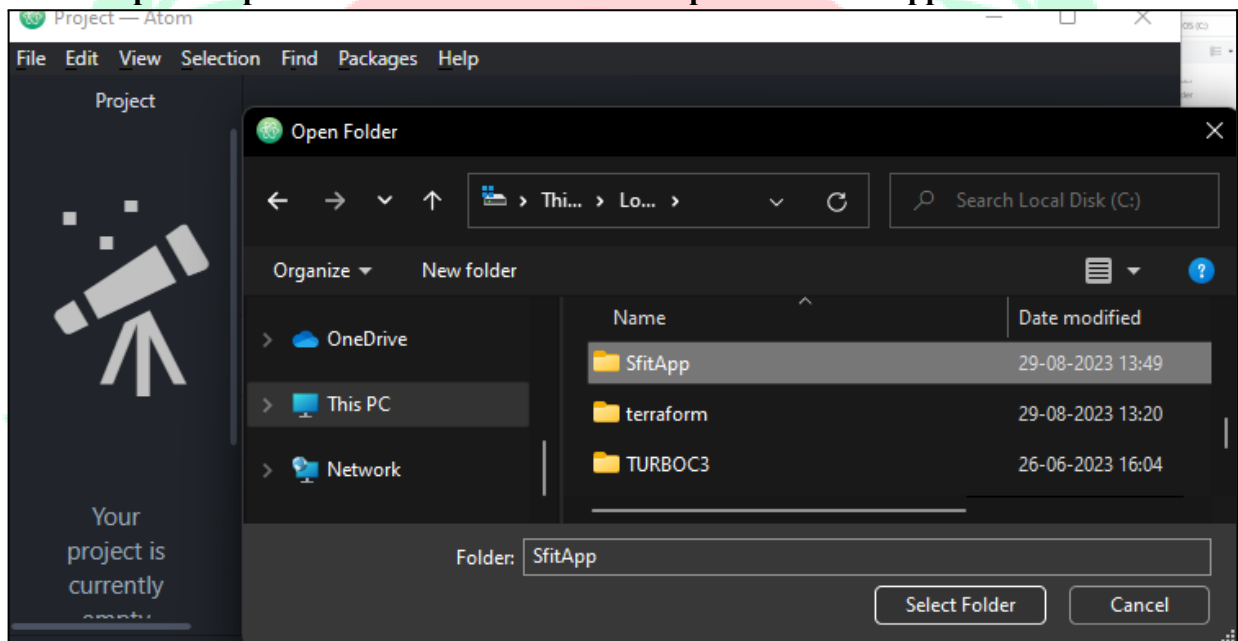

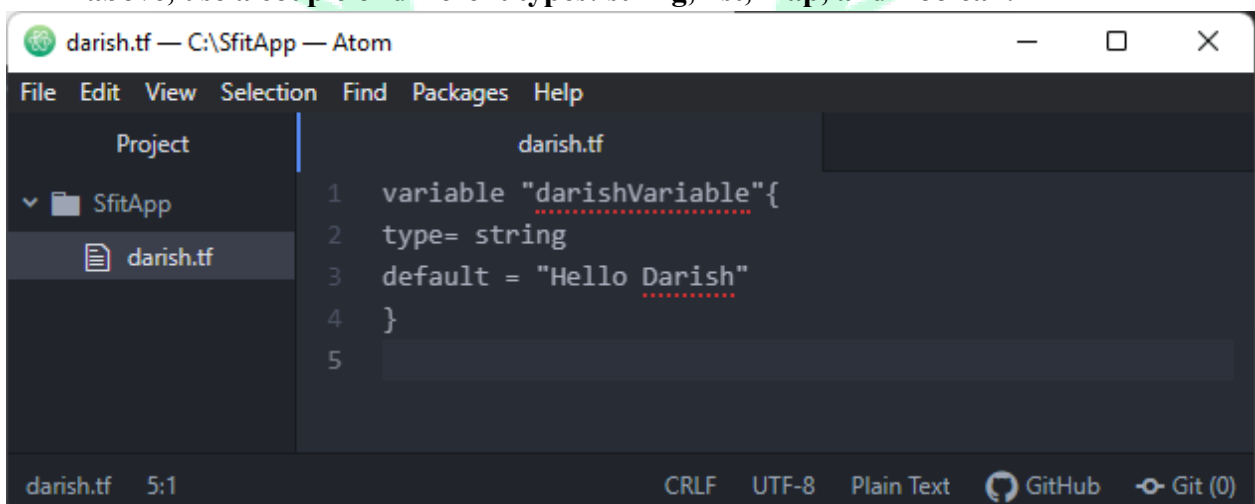

The available commands for execution are listed below.
The primary workflow commands are given first, followed by
less common or more advanced commands.

Main commands:
  init       Prepare your working directory for other commands
  validate   Check whether the configuration is valid
  plan       Show changes required by the current configuration
  apply      Create or update infrastructure
  destroy    Destroy previously-created infrastructure

All other commands:
  console    Try Terraform expressions at an interactive command prompt
  fmt        Reformat your configuration in the standard style
  force-unlock Release a stuck lock on the current workspace
  get        Install or upgrade remote Terraform modules
  graph      Generate a Graphviz graph of the steps in an operation
  import     Associate existing infrastructure with a Terraform resource
  login      Obtain and save credentials for a remote host
  logout     Remove locally-stored credentials for a remote host
  metadata   Metadata related commands
  output     Show output values from your root module
  providers  Show the providers required for this configuration
  refresh    Update the state to match remote systems
  show       Show the current state or a saved plan
  state      Advanced state management
  taint      Mark a resource instance as not fully functional
  test       Experimental support for module integration testing
  untaint    Remove the 'tainted' state from a resource instance
  version    Show the current Terraform version
  workspace  Workspace management

Global options (use these before the subcommand, if any):
  -chdir=DIR  Switch to a different working directory before executing the
              given subcommand.
  -help       Show this help output, or the help for a specified subcommand.
  -version    An alias for the "version" subcommand.

PS C:\Windows\system32>
```

Step 11: Create a folder c:\SfitApp**Step 12 : Open Atom/VS CODE Editor ...Open folder SfitApp****Step 13: write main.tf file with input variables. The input variables, like the one above, use a couple of different types: string, list, map, and Boolean.**

```

Administrator: Windows PowerShell
PS C:\Windows\system32> terraform console
> var.Myvariable

Error: Reference to undeclared input variable

  on <console-input> line 1:
  (source code not available)

An input variable with the name "Myvariable" has not been declared. This variable
can be declared with a variable "Myvariable" {} block.

> ^C
PS C:\Windows\system32> cd C:\SfitApp
PS C:\SfitApp> terraform console
> var.darishVariable
"Hello Darish"
>

```

Step 14: Check the output on command Prompt...Go to C:\SfitApp, Type Terraform Console You will get terraform prompt, run the .tf with var.MyVariable1, You will get welcome to SFIT msg. Step 15: try Boolean variable...Create Boolean.tf

```

Project      darish.tf      dar-boolean.tf
└─ SfitApp
   .terraform.tfstate
   dar-boolean.tf
1  variable "Password"{default = false}
2
PS C:\SfitApp> terraform console
> var.Password
false

```

8. Post-Experiments Exercise

A. Extended Theory:

- Terraform Vs. Kubernetes
- Terraform Vs. Ansible

B. Questions:

1. Name all version controls supported by Terraform.
2. What is TerraGrunt?

C. Conclusion:

Write the significance of the topic studied in the experiment.
